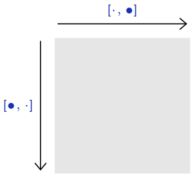
A tensor can be of several types:

- `torch.float16`, `torch.float32`, `torch.float64`,
- `torch.uint8`,
- `torch.int8`, `torch.int16`, `torch.int32`, `torch.int64`

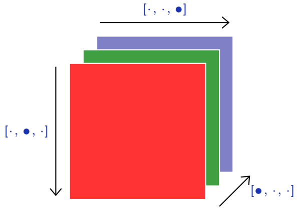
and can be located either in the CPU's or in a GPU's memory. Operations on tensors located in device's memory are done by that device. We will come back to that later.

```
>>> x = torch.zeros(1, 3)
>>> x.dtype, x.device
(torch.float32, device(type='cpu'))
>>> x = x.long()
>>> x.dtype, x.device
(torch.int64, device(type='cpu'))
>>> x = x.cuda()
>>> x.dtype, x.device
(torch.int64, device(type='cuda', index=0))
```

2d tensor (*e.g.* grayscale image)



3d tensor (*e.g.* rgb image)



$[\cdot, \cdot, \bullet]$
$[\cdot, \bullet, \cdot]$
$[\bullet, \cdot, \cdot]$

4d tensor (*e.g.* sequence of rgb images)

Broadcasting

Broadcasting automagically expands dimensions by replicating coefficients, when it is necessary to perform operations.

Broadcasting automagically expands dimensions by replicating coefficients, when it is necessary to perform operations.

For instance:

```
>>> x = torch.empty(100, 4).normal_(2)
>>> x.mean(0)
tensor([2.0476, 2.0133, 1.9109, 1.8588])
>>> x -= x.mean(0)
>>> x.mean(0)
tensor([-4.0531e-08, -4.4703e-07, -1.3471e-07,  3.5763e-09])
```

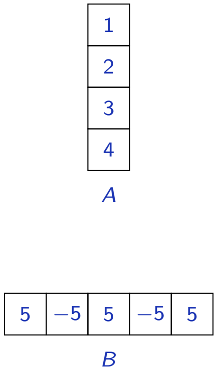
1. If one of the tensors has fewer dimensions than the other, it is reshaped by adding as many dimensions of size 1 as necessary in the front; then
2. for every mismatch, **if one of the two tensor is of size one,** it is expanded along this axis by replicating coefficients.

If there is a tensor size mismatch for one of the dimension and neither of them is one, the operation fails.

```
A = torch.tensor([[1.], [2.], [3.], [4.]])
B = torch.tensor([[5., -5., 5., -5., 5.]])
C = A + B
```



```
A = torch.tensor([[1.], [2.], [3.], [4.]])

C = A + B
```
